Price Controls

- **Price ceiling:** illegal to sell above the specified price.
 - Rent controls, anti price-gouging laws
 - Creates a gap in quantity demanded and quantity supplied (shortage): $Q^D > Q^S$.
- **Price floor:** illegal to sell below the specified price.
 - Minimum wage
 - Also creates a gap in quantity demanded and supplied (surplus): $Q^D < Q^S$.
- If the original equilibrium is already in compliance with the price control, then we say the price control is **non-binding** – it has no effect.

Exercise 1: Price Controls

Consider the orange juice market:

- Demand: $Q^D = 50 - P$
 - Supply: $Q^S = 4P$
- 1 Without government intervention, what are the equilibrium price and quantity?
 - 2 Suppose now the government imposes a price ceiling of \$8 to this market. Will there be a shortage or surplus? Calculate the shortage/surplus if it exists.
 - 3 Suppose the price ceiling is \$12. Will there be a shortage or surplus? Calculate the shortage/surplus if it exists.

Exercise 1: Price Controls

Solution:

- 1 In equilibrium, quantity demanded equals quantity supplied at the equilibrium price:
 $Q^D(P) = Q^S(P)$. This gives us:

$$50 - P = 4P$$

$$Q = 40, P = 10$$

- 2 Under the price ceiling, $Q^D = 50 - 8 = 42$, $Q^S = 4 \times 8 = 32$. Since the quantity demanded is larger than the quantity supplied, we have a shortage of $42 - 32 = 10$.
- 3 No shortage or surplus since the price ceiling is not binding.

Taxes

- Creates a gap between the price paid by the buyer P^D , and the price received by the seller P^S .
- Suppose the government imposes a tax of size t on buyers.
 \implies Condition 1: $P^D = P^S + t$
- To find new equilibrium, we set

$$\begin{aligned}Q^D(P^D) &= Q^S(P^S) \\ Q^D(P^S + t) &= Q^S(P^S)\end{aligned}$$

- Suppose the government instead imposes a tax of size t on sellers.
 \implies Condition 2: $P^S = P^D - t$
- But this is equivalent to Condition 1! So we can find the new equilibrium using the same setup:

$$\begin{aligned}Q^D(P^D) &= Q^S(P^S) \\ Q^D(P^S + t) &= Q^S(P^S)\end{aligned}$$

Punchline: The resulting equilibrium prices and quantity are the same whether the tax is imposed on buyers or sellers.

Exercise 2: Tax

Consider the yogurt market:

- Demand: $Q^D = 400 - 10P$
- Supply: $Q^S = 30P - 800$

- 1 Without government intervention, what are the equilibrium price and quantity?
- 2 Suppose now the government imposes a tax of \$4 per unit to the buyers. What are the new equilibrium prices and quantity?
- 3 How is the tax split between buyers and sellers? What role does elasticity play in this?

Exercise 2: Tax

Solution:

- ① In equilibrium, quantity demanded equals quantity supplied at the equilibrium price: $Q^D(P) = Q^S(P)$. This gives us:

$$400 - 10P = 30P - 800$$

$$Q = 100, P = 30$$

- ② The price paid by buyers is $P^D = P^S + 4$, and the price received by sellers is P^S . In equilibrium, quantity demanded at the price paid by buyers equals to quantity supplied at the price received by sellers. This gives us:

$$Q^D(P^D) = Q^S(P^S)$$

$$Q^D(P^S + 4) = Q^S(P^S)$$

$$400 - 10(P^S + 4) = 30P^S - 800$$

$$P^S = 29, P^D = 33, Q = 70$$

- ③ Compared to the market without tax, the price paid by buyers increases from \$30 to \$33, so the tax shared by buyers is \$3. Similarly, the price received by sellers decreases from \$30 to \$29, and the tax shared by sellers is \$1. The agent with the more elastic (flatter) curve will pay less of the tax.

- The opposite of a tax: for every unit sold, the government *contributes* money rather than takes it.
- Consider a subsidy to buyers of size σ .
 \implies Condition 3: $P^D = P^S - \sigma$
- Likewise, a subsidy to sellers of size σ .
 \implies Condition 4: $P^S = P^D + \sigma$.
- As before, the two conditions are equivalent, so **the resulting prices and quantity are the same either way.**
- To solve, set

$$\begin{aligned}Q^D(P^D) &= Q^S(P^S) \\ Q^D(P^S - \sigma) &= Q^S(P^S)\end{aligned}$$

Exercise 3: Subsidy

Consider the market for corn:

- $Q^D = 152 - 7P$
- $Q^S = P - 8$

- 1 What are the original equilibrium price and quantity?
- 2 Suppose the government offers a subsidy of \$8 per unit to the sellers. What are the new equilibrium prices and quantity?
- 3 How are the benefits of the subsidy split between buyers and sellers? What role does elasticity play here?

Exercise 3: Subsidy

Solution:

- ① In equilibrium,

$$\begin{aligned}Q^D(P) &= Q^S(P) \\152 - 7P &= P - 8 \\P &= 20, Q = 12\end{aligned}$$

- ② With a subsidy $\sigma = 8$ to sellers, we know $P^S = P^D + 8$. So set

$$\begin{aligned}Q^D(P^D) &= Q^S(P^S) \\Q^D(P^D) &= Q^S(P^D + 8) \\152 - 7P^D &= (P^D + 8) - 8 \\P^D = 19, P^S = 27, Q &= 19\end{aligned}$$

- ③ Compared the the original equilibrium, consumers pay \$1 less, and sellers receive \$7 more. The agent with the more elastic (flatter) curve will receive less of the subsidy.
